---

`c2cv`

*Comparison of 2 values of species richness using a randomization*

---

## Description

Species richnesses are computed as the cumulative value over all samples. Richnesses are compared by means of a randomization test without controlling for differences of sampling regime or communities density.

## Usage

```
c2cv (com1, com2, nrandom=99, pr1=0.025, pr2=0.975, verbose=TRUE)
```

## Arguments

<code>com1</code>	A first species-sample matrix (community 1). Rows correspond to samples whereas columns stand for species.
<code>com2</code>	A second species-sample matrix (community 2). Rows correspond to samples whereas columns stand for species.
<code>nrandom</code>	Number of randomizations to be performed. Default fixed to 99.
<code>pr1</code>	Lower probability level for quantile computations. Default fixed to 0.025.
<code>pr2</code>	Higher probability level for quantile computations. Default fixed to 0.975.
<code>verbose</code>	If <code>verbose</code> is <code>TRUE</code> <code>c2cv</code> returns a vector that contains the observed and randomized differences between richnesses.

## Details

If the observed richness for community 1  $\geq$  observed value for community 2, `c2cv` returns a probability  $p$  estimated as the number of randomizations for which the observed value for community 1  $\geq$  observed value for community 2 divided by the number of randomization + 1. Similarly, if the observed value for community 1  $\leq$  observed value for community 2,  $p$  corresponds to the frequency of such situation in the randomizations.

**Value**

If `verbose==TRUE` `c2cm` returns a data frame and a vector with the randomized values. Otherwise, only the data frame is returned.

<code>res</code>	<p>A data frame with the outputs of the randomization test:</p> <ul style="list-style-type: none"> <li><code>cv1</code> Observed cumulative richness for community 1.</li> <li><code>cv2</code> Observed cumulative richness for community 2.</li> <li><code>cv1-cv2</code> Difference between observed cumulative richness of community 1 and community 2.</li> <li><code>p</code> Probability of encountering such a value for <code>cv1-cv2</code> (see details above).</li> <li><code>quantile for pr1</code> Quantile value for probability level <code>pr1</code>.</li> <li><code>quantile for pr2</code> Quantile value for probability level <code>pr2</code>.</li> <li><code>randomized cv1-cv2</code> Mean values of randomized and the observed values.</li> <li><code>nrandom</code> Number of randomizations used in the test.</li> </ul>
<code>rand</code>	<p>A vector of <code>nrandom+1</code> values corresponding to the observed difference of <code>cv1-cv2</code> and the randomized values. <code>rand</code> is available if <code>verbose == TRUE</code>.</p>

**Note**

The observed difference between populations is included in the numerator and the denominator when computing the probability `p`. This is justified because if the null hypothesis (there is no difference between populations) is true then the observed difference between populations is just another value for the randomization distribution (Manly, 1997, p. 7).

**Author(s)**

**Examples**

```
data(efeb)
c2cv(com1=efeb$ef, com2=efeb$eb, nrandom=49, verbose=FALSE)
```

c2m

*Compares 2 mean values using a randomization test***Description**

Mean values of 2 populations are compared using a randomization procedure. Overlapping populations are allowed.

**Usage**

```
c2m(pop1, pop2, pop3=NULL, nrandom, pr1=0.025, pr2=0.975, verbose=TRUE)
```

**Arguments**

pop1	A vector with the observed values for population 1.
pop2	A vector with the observed values for population 2.
pop3	A vector with the observed values that are common to population 1 and 2.
nrandom	Number of randomizations to perform. Default fixed to 99.
pr1	Lower probability level for quantile computations. Default fixed to 0.025.
pr2	Higher probability level for quantile computations. Default fixed to 0.975.
verbose	If <code>verbose</code> is <code>TRUE</code> <code>c2m</code> returns a vector that contains the observed and randomized differences between mean richnesses.

**Details**

This randomization test compares the average value of a quantitative variable sampled in 2 populations. Details are available in Manly (1997). In some cases, populations share some observed values: for example if we compare the mean annual temperature of sites where either species A or B is present and if A and B are sympatric in some localities (see example below). Those shared values are passed to `c2m` by the argument `pop3`.

If the mean value for population 1  $\geq$  mean value for population 2, `p` is the number of randomizations for which the mean value for population 1  $\geq$  mean value for population 2 divided by the number of randomizations + 1. If the mean value for population 1  $\leq$  mean value for population 2, `p` is the number of randomizations for which the mean value for population 1  $\leq$  mean value for population 2 divided by the number of randomizations + 1. If mean value for population 1 = mean value for population 2 `p` is not computed (`p=NC`).

**Value**

res	A data frame showing the outputs of the randomization test:
mv1	Observed mean values over samples forming population 1.
mv2	Observed mean values over samples forming population 2.
mv1-mv2	Difference between observed mean values of population 1 and population 2.
p	Probability of encountering such a value for <code>mv1-mv2</code> (see details above).

`quantile for pr1` Quantile value for probability level `pr1`.  
`quantile for pr2` Quantile value for probability level `pr2`.  
`randomized mv1-mv2` Mean values of randomized and the observed values.  
`nrandom` Number of randomizations used in the test.

`rand` A vector of `nrandom+1` values corresponding to the observed difference of `mv1-mv2` and the randomized values. `rand` is available if `verbose == TRUE`.

### Note

The observed difference between populations is included in the numerator and the denominator when computing the probability  $p$ . This is justified because if the null hypothesis (there is no difference between populations) is true then the observed difference between populations is just another value for the randomization distribution (Manly, 1997, p. 7).

```

```
nrandom=49, verbose=FALSE)
```

---

c2rcv *Compares the cumulative richness of two communities and rescales the*

---

### Description

c2rcv first rarefies the richness of the community with highest density to get an estimation of its richness for a density comparable to that of the community with lower density. A randomization test is then performed on the difference between these richnesses. Randomizations are performed under the constraint that the resulting density for both communities is comparable to that of the community with lower density.

### Usage

```
c2rcv(com1, com2, nrandom, tolerance=0.1, pr1=0.025, pr2=0.975, verbose=FALSE)
```

### Arguments

com1	A first species-sample matrix (community 1). Rows correspond to samples whereas columns stand for species.
com2	A second species-sample matrix (community 2). Rows correspond to samples whereas columns stand for species.
nrandom	Number of randomizations to be performed. Default fixed to 99.
tolerance	A number used to calculate the range of acceptable values for the density of simulated communities. Let $D$ be largest density (com1 or com2). The acceptable interval is $D \pm tolerance \times D$ .
pr1	Lower probability level for quantile computations. Default fixed to 0.025.
pr2	Higher probability level for quantile computations. Default fixed to 0.975.
verbose	If <code>verbose==TRUE</code> the function returns detailed randomization outputs.

### Details

The function calls [raref2](#) to rarefy the species richness of the community with higher density.

### Value

dmean	The mean value of the difference between the rarefied cumulative richness and the observed cumulative richness in the other community.
q1	First quantile for the distribution of randomized values of dmean.
q2	Second quantile for the distribution of randomized values of dmean.

If `verbose==TRUE`, c2rcv returns 6 additional records of length equal to the number of randomization:

d	A vector of length <code>nrandom</code> containing the values of the differences between the rarefied cumulative richness and the observed cumulative richness in the other community for each randomization.
drand	A vector of length <code>nrandom</code> containing the values of the randomized differences between the rarefied cumulative richness and the observed cumulative richness in the other community.
rarefied	A vector of length <code>nrandom</code> containing the density of the community with the largest initial density after rarefaction. These values are as close to the density of the community with lower density as the parameter <code>tolerance</code> is low.
lowerD	The density of the community with lower density. This value is constant.
rarefiedS	A vector of length <code>nrandom</code> containing the cumulative richness of the rarefied community. These values are to be compared with <code>lowerDS</code> .
lowerDS	Cumulative richness of the community with lower density.

### Note

The observed difference between populations is included in the numerator and the denominator when computing the probability  $p$ . This is justified because if the null hypothesis (there is no difference between populations) is true then the observed difference between populations is just another value for the randomization distribution (Manly, 1997, p. 7). The results are sensitive to the value of the `tolerance` parameter.

ea

*Soil macrofauna in a tropical field under traditional slash-and-burn*

---

### Description

The `ea` data set is a data frame describing the species abundance of soil macrofauna in a set of soil samples collected in a field (aka abattis) in French Guiana. These data were collected in the vicinity of the Wayana village of Elahe situated on the Tampoc river.

### Usage

```
data(ea)
```

### Format

`ea` is a data frame containing the observations of 45 species (columns) at 30 sampling locations (rows).

### Source

Decreasing fallow duration in tropical slash-and-burn agriculture alters soil macro-invertebrate diversity: A case study in southern French Guiana. *Agriculture, Ecosystems and Environment* 135, 148-154.

### Examples

```
## Estimating species richness using rich
data(ea)
rich(matrix=ea)
```

---

efea

*Soil macrofauna in a tropical forest site and cultivated plot*

---

### Description

The `efea` data set is a list of two data sets. Each one is a data frame giving the species abundance of soil macrofauna in a set of soil samples. `efea$ef` corresponds to samples collected in a secondary forest in French Guiana while `efea$ea` contains data collected in in a field (aka abattis) in French Guiana. These data were collected in the vicinity of the Wayana village of Elahe situated on the Tampoc river.

### Usage

```
data(efea)
```

**Format**

`efea` is a list of two data frame containing the observations of 142 species (columns) at 30 sampling locations (rows).

**Source**

---

`efeb`

*Soil macrofauna in a tropical forest site before and after*

---

**Description**

The `efeb` data set is a list of two data sets. Each one is a data frame giving the species abundance of soil macrofauna in a set of soil samples. `efeb$ef` corresponds to samples collected in a secondary forest in French Guiana while `efeb$eb` contains data collected in the same site just after the forest has been cut and burnt following the traditional Amerindian slash-and-burn system. These data were collected in the vicinity of the Wayana village of Elahe situated on the Tampoc river.

**Usage**

```
data(efeb)
```

**Format**

`efeb` is a list of two data frame containing the observations of 134 species (columns) at 30 sampling locations (rows).

**Source**

```
## Estimating species richness using rich
data(ef)
rich(matrix=ef)
```

---

`rarc`*Computes rarefaction curves*

---

**Description**

`c` computes rarefaction curves and returns a data frame with bootstrap estimates of species richness and average number of individuals for a given sample size.

**Usage**

```
rarc(matrix, samplesize=NULL, nrandom=99)
```

### Arguments

<code>matrix</code>	<code>matrix</code> is a typical species-sample matrix. Rows correspond to samples whereas columns stand for species.
<code>samplesize</code>	A vector containing the different sample sizes for which the computations are required. If missing or non vector, <code>samplesize</code> is replaced by a sequence from 1 to the maximum possible sample size given the size of <code>matrix</code> .
<code>nrandom</code>	<code>nrandom</code> is the number of a randomizations used in the bootstrap estimation. Values of <code>nrandom</code> <10 or NULL are set to 99.

### Details

`rarc` performs bootstrap that is resampling with replacement. This strategy was chosen because the variance among randomizations remains meaningful even at the right-hand of the accumulation curve. This condition is necessary, for example when one aims at comparing species richnesses.

### Value

A data frame giving the bootstrap estimate of the richness, number of individuals associated to different number of sampling units.

### Author(s)

Jean-Pierre Rossi <jean-pierre.rossi@supagro.inra.fr>

```

---

`raref2`

*Estimates the species richness for a given number of sampled*

---

### Description

`raref2` computes an estimation of the species richness by thinning the data matrix so that the overall corresponding density is comprised in a fixed interval.

### Usage

```
raref2(matrix, dens, tolerance, nrandom=99)
```

**Arguments**

<code>matrix</code>	<code>matrix</code> is a typical species-sample matrix. Rows correspond to samples whereas columns stand for species.
<code>dens</code>	A number corresponding to the density for which a species richness estimation is required. <code>dens</code> must be comprised within the range of the observed density.
<code>tolerance</code>	A number used to calculate the range of acceptable values for the density of simulated communities. Let $D$ be largest density (com1 or com2). The acceptable interval is $D \pm tolerance \times D$ .
<code>nrandom</code>	<code>nrandom</code> is the number of a randomizations used in the bootstrap estimation. Values of <code>nrandom</code> <10 or NULL are set to 99.

**Details**

`raref2` performs bootstrap that is resampling with replacement. This strategy was chosen because the variance among randomizations remains meaningful even at the right-hand of the accumulation curve. This condition is necessary, for example when one aims at comparing species richnesses.

**Value**

`raref2` returns a list with two components.

<code>mean.boot</code>	The mean value of the bootstrap estimates of the species richness.
<code>sd.boot</code>	The standard deviation of the bootstrap estimates.

**Author(s)**

raref2(matrix=ef, dens=1100, tolerance=0.01, nrandom=49)
```

---

`raref`

*Estimates the species richness for a given number of sampled*

---

**Description**

`raref` computes rarefaction curve and interpolates the species richness corresponding to a given density of individuals.

**Usage**

```
raref(matrix, dens, nrandom=99)
```

**Arguments**

<code>matrix</code>	<code>matrix</code> is a typical species-sample matrix. Rows correspond to samples whereas columns stand for species.
<code>dens</code>	A number corresponding to the density for which a species richness estimation is required. <code>dens</code> must be comprised within the range of the observed density.
<code>nrandom</code>	<code>nrandom</code> is the number of a randomizations used in the bootstrap estimation. Values of <code>nrandom</code> <10 or NULL are set to 99.

**Details**

`raref2` performs bootstrap that is resampling with replacement. This strategy was chosen because the variance among randomizations remains meaningful even at the right-hand of the accumulation curve. This condition is necessary, for example when one aims at comparing species richnesses.

**Value**

`raref` returns a list with two components.

<code>rar</code>	A data frame with three columns giving the observed species richness for different sample size and corresponding density of individuals.
<code>Sinterp</code>	A vector with the term <code>dens</code> and the corresponding interpolated species richness.

---

rich *Species richness, their confidence interval and other useful indices*

---

### Description

Computes the cumulative and average species richness over a set of samples, the associated bootstrap statistics and other useful indices.

### Usage

```
rich(matrix, verbose = FALSE, nrandom = NULL)
```

### Arguments

matrix	matrix is a typical species-sample matrix. Rows correspond to samples whereas columns stand for species.
verbose	If verbose=FALSE, a simplified output is returned.
nrandom	Number of randomizations if bootstrap estimations are required. Non-null values < 10 are set to 99.

### Details

rich computes basic descriptive statistics from typical species by sample data sets.

### Value

cr	Cumulated richness over sampling units.
mr	Mean richness over sampling units.
mrsd	Standard deviation of the mean richness.
singletons	Species with at most one observation.
doubletons	Species with at most two observations.
uniques	Species encountered in only one sample.
duplicates	Species encountered in only two samples.
bootCR	A data frame showing the outputs of the bootstrap analyses of the cumulative richness (computed if nrandom != FALSE): cr.obs Observed cumulative richness, equal to cr above. cr.boot Mean of the bootstrap values. cr.bcorr Mean of the bootstrap values corrected for the bias estimated below. cr.bias Bias. cr.se Standard error of the cumulative richness estimated by bootstrap. This is estimated as the standard deviation of the bootstrap values. cr.lbn Lower bound of the first order normal approximation confidence interval (see <code>boot.ci</code> {boot}).

	<code>cr.ubn</code>	Upper bound of the first order normal approximation confidence interval (see <code>boot.ci</code> {boot}).
<code>bootMR</code>		A data frame showing the outputs of the bootstrap analyses of the mean richness (computed if <code>nrandom != FALSE</code> ): <code>mr.obs</code> Observed mean richness, equal to <code>mr</code> above. <code>mr.boot</code> Mean of the bootstrap values. <code>mr.bcorr</code> Mean of the bootstrap values corrected for the bias estimated below. <code>mr.bias</code> Bias. <code>mr.se</code> Standard error of the mean richness estimated by bootstrap. This is estimated as the standard deviation of the bootstrap values. <code>mr.lbn</code> Lower bound of the first order normal approximation confidence interval (see <code>boot.ci</code> {boot}). <code>mr.ubn</code> Upper bound of the first order normal approximation confidence interval (see <code>boot.ci</code> {boot}).
	<code>nrandom</code>	Number of randomizations used in the bootstrap.
	<code>richvec</code>	A vector containing the observed richness in each sample or populations. The mean of <code>richvec</code> corresponds to <code>mr</code> (available if <code>verbose == TRUE</code> ).
	<code>matrix</code>	The data set passed to <code>rich</code> as the <code>matrix</code> argument (available if <code>verbose == TRUE</code> ).
	<code>matrixbin</code>	Binary (presence/absence) transformation of the data set passed to <code>rich</code> as the <code>matrix</code> argument (available if <code>verbose == TRUE</code> ).
	<code>sumrow</code>	A vector of the sum of species for each sample (available if <code>verbose == TRUE</code> ).
	<code>sumcol</code>	A vector of the sum of sample for each species (available if <code>verbose == TRUE</code> ).
	<code>zeroes</code>	Number of zeroes in the data set (available if <code>verbose == TRUE</code> ).

---

shared	<i>Computes the number of species shared by groups of sampling units and</i>
--------	------------------------------------------------------------------------------

---

### Description

shared computes the richness of each group of sample depicting a community, the number of species shared by pairs of communities and the total number of species for each pairs of community.

### Usage

```
shared(lmatrix)
```

### Arguments

lmatrix	A list of data matrices representing the species composition of local communities. All matrices must have the same size.
---------	--------------------------------------------------------------------------------------------------------------------------

### Value

A data frame with: on the diagonal the observed richness for each local community, above the diagonal: the richness common to pairs of communities (shared richness) and below the diagonal: the total richness for pooled pairs of communities.

### Author(s)
